Chapter 1

About

1.1 The Book

Statistical methods for networked systems are present in most disciplines. Nonetheless, the "language barrier" we may face when communicating with our fellow scientists, many of the methods developed to study specific types of problems can indeed be helpful outside of their original context.

This project began as a part of a workshop that took place at USC's Center for Applied Network Analysis. Now, it is a personal project that I use to gather and study statistical methods used for analyzing networks, emphasizing social and biological systems. Moreover, the book will use statistical computing methods as a core component when developing these topics.

In general, we will, besides R itself, we will be using R studio and the following R packages: dplyr for data management, stringr for data cleaning, and of course igraph, netdiffuseR (a bit of a bias here), and statnet for our neat network analysis.¹

You can access the book's source code at https://github.com/gvegayon/appliedsnar.

1.2 The author

I am a Research Programmer at USC's Department of Population and Public Health Sciences, where I work on studying Complex Systems using Statistical Computing. I have over ten years of experience developing scientific software focusing on high-performance computing, data visualization, and social network analysis. My training is in Public Policy (M.A. UAI, 2011), Economics (M.Sc. Caltech, 2015), and Biostatistics (Ph.D. USC, 2020).

I obtained my Ph.D. in Biostatistics under the supervision of Prof. Paul Marjoram and Prof. Kayla

¹Some of you may be wondering "what about ggplot2 and friends? What about tidyverse", well, my short answer is I jumped into R before all of that was that popular. When I started, plots were all about lattice, and after a couple of years on that, about base R graphics. What I'm saying is that so far, I have not found a compelling reason to leave my "old practices" and embrace all the tidyverse movement (religion?).

6 CHAPTER 1. ABOUT

de la Haye, with my dissertation titled "Essays on Bioinformatics and Social Network Analysis: Statistical and Computational Methods for Complex Systems."

If you'd like to learn more about me, please visit my website at https://ggvy.cl.

Chapter 2

Introduction

Social Network Analysis and Network Science, have a long scholarly tradition. From social diffusion models to protein-interaction networks, these complex-systems disciplines cover a wide range of problems across scientific fields. Yet, although these could be seen as wildly different, the object under the microscope is the same, networks.

With a long history (and insufficient levels of inter-discipline collaboration, if you allow me to say) of scientific advances happing in a somewhat isolated fashion, the potential of cross-pollination between disciplines within network science is immense.

This book is an attempt to compile the many methods available in the realm of complexity sciences, provide an in-depth mathematical examination—when possible—, and provide a few examples illustrating their usage.

Chapter 3

R Basics

3.1 What is R

A good reference book for both new and advanced user is "The Art of R programming" (Matloff 2011)¹

3.2 How to install packages

Nowadays there are two ways of installing R packages (that I'm aware of), either using install.packages, which is a function shipped with R, or use the devtools R package to install a package from some remote repository other than CRAN, here is a couple of examples:

```
# This will install the igraph package from CRAN
> install.packages("netdiffuseR")

# This will install the bleeding-edge version from the project's github repo!
> devtools::install_github("USCCANA/netdiffuseR")
```

The first one, using install.packages, installs the CRAN version of netdiffuseR, whereas the second installs whatever version is plublished on https://github.com/USCCANA/netdiffuseR, which is usually called the development version.

In some cases users may want/need to install packages from command line as some packages need extra configuration to be installed. But we won't need to look at it now.

3.3 Prerequisits

To install R just follow the instructions available at http://cran.r-project.org

¹Here a free pdf version distributed by the author.

RStudio is the most popular Integrated Development Environment (IDE) for R that is developed by the company of the same name. While having RStudio is not a requirement for using netdiffuseR, it is highly recommended.

To get RStudio just visit https://www.rstudio.com/products/rstudio/download/.

3.4 A gentle Quick n' Dirty Introduction to R

Some common tasks in R

0. Getting help (and reading the manual) is *THE MOST IMPORTANT* thing you should know about. For example, if you want to read the manual (help file) of the read.csv function, you can type either of these:

```
?read.csv
?"read.csv"
help(read.csv")
```

If you are not fully aware of what is the name of the function, you can always use the fuzzy search

```
help.search("linear regression")
??"linear regression"
```

1. In R you can create new objects by either using the assign operator (<-) or the equal sign =, for example, the following 2 are equivalent:

```
a <- 1
a = 1
```

Historically the assign operator is the most common used.

2. R has several type of objects, the most basic structures in R are vectors, matrix, list, data.frame. Here is an example creating several of these (each line is enclosed with parenthesis so that R prints the resulting element):

```
##
        [,1] [,2] [,3]
## [1,]
          1
## [2,]
          2
                5
                     8
                     9
## [3,]
        3
                6
(a_string_mat <- matrix(letters[1:9], ncol=3)) # Matrices can be of strings too
##
        [,1] [,2] [,3]
## [1,] "a" "d" "g"
## [2,] "b" "e" "h"
## [3,] "c" "f" "i"
(another_mat <- cbind(1:4, 11:14)) # The `cbind` operator does "column bind"</pre>
##
        [,1] [,2]
## [1,]
          1
              11
## [2,]
          2
               12
## [3,]
          3
               13
        4 14
## [4,]
(another_mat2 <- rbind(1:4, 11:14)) # The `rbind` operator does "row bind"</pre>
##
        [,1] [,2] [,3] [,4]
              2
## [1,]
         1
                     3
## [2,]
         11
               12
                    13
                         14
(a_string_mat <- matrix(letters[1:9], ncol = 3))</pre>
##
        [,1] [,2] [,3]
## [1,] "a" "d" "g"
## [2,] "b" "e" "h"
## [3,] "c" "f" "i"
(a_list
         <- list(a_vector, a_matrix))
## [[1]]
## [1] 1 2 3 4 5 6 7 8 9
##
## [[2]]
        [,1] [,2] [,3]
##
## [1,]
          1
                4
## [2,]
          2
                5
                     8
        3
                     9
## [3,]
                6
(another_list <- list(my_vec = a_vector, my_mat = a_matrix)) # same but with names!</pre>
## $my_vec
## [1] 1 2 3 4 5 6 7 8 9
##
```

```
## $my_mat
          [,1] [,2] [,3]
  ##
  ## [1,]
            1
            2
                  5
                       8
  ## [2,]
                  6
                       9
  ## [3,]
             3
  # Data frames can have multiple types of elements, it is a collection of lists
  (a_data_frame \leftarrow data.frame(x = 1:10, y = letters[1:10]))
  ##
         х у
  ## 1
         1 a
  ## 2
        2 b
  ## 3
        3 c
  ## 4
       4 d
  ## 5
        5 e
        6 f
  ## 6
  ## 7 7 g
  ## 8
       8 h
  ## 9
       9 i
  ## 10 10 j
3. Depending on the type of object, we can access to its components using indexing:
  a_vector[1:3] # First 3 elements
  ## [1] 1 2 3
  a_string_vec[3] # Third element
  ## [1] "netdiffuseR"
  a_matrix[1:2, 1:2] # A sub matrix
  ##
          [,1] [,2]
  ## [1,]
             1
  ## [2,]
                  5
             2
  a_matrix[,3] # Third column
  ## [1] 7 8 9
  a_matrix[3,] # Third row
  ## [1] 3 6 9
  a_string_mat[1:6] # First 6 elements of the matrix. R stores matrices by column.
  ## [1] "a" "b" "c" "d" "e" "f"
  # These three are equivalent
  another_list[[1]]
```

```
## [1] 1 2 3 4 5 6 7 8 9
  another_list$my_vec
  ## [1] 1 2 3 4 5 6 7 8 9
  another_list[["my_vec"]]
  ## [1] 1 2 3 4 5 6 7 8 9
  # Data frames are just like lists
  a_data_frame[[1]]
  ## [1] 1 2 3 4 5 6 7 8 9 10
  a_data_frame[,1]
  ## [1] 1 2 3 4 5 6 7 8 9 10
  a_data_frame[["x"]]
  ## [1] 1 2 3 4 5 6 7 8 9 10
  a_data_frame$x
  ## [1] 1 2 3 4 5 6 7 8 9 10
4. Control-flow statements
  # The oldfashion forloop
  for (i in 1:10) {
    print(paste("I'm step", i, "/", 10))
  }
  ## [1] "I'm step 1 / 10"
  ## [1] "I'm step 2 / 10"
  ## [1] "I'm step 3 / 10"
  ## [1] "I'm step 4 / 10"
  ## [1] "I'm step 5 / 10"
  ## [1] "I'm step 6 / 10"
  ## [1] "I'm step 7 / 10"
  ## [1] "I'm step 8 / 10"
  ## [1] "I'm step 9 / 10"
  ## [1] "I'm step 10 / 10"
  # A nice ifelse
  for (i in 1:10) {
    if (i %% 2) # Modulus operand
      print(paste("I'm step", i, "/", 10, "(and I'm odd)"))
```

```
else
    print(paste("I'm step", i, "/", 10, "(and I'm even)"))
}
## [1] "I'm step 1 / 10 (and I'm odd)"
## [1] "I'm step 2 / 10 (and I'm even)"
## [1] "I'm step 3 / 10 (and I'm odd)"
## [1] "I'm step 4 / 10 (and I'm even)"
## [1] "I'm step 5 / 10 (and I'm odd)"
## [1] "I'm step 6 / 10 (and I'm even)"
## [1] "I'm step 7 / 10 (and I'm odd)"
## [1] "I'm step 8 / 10 (and I'm even)"
## [1] "I'm step 9 / 10 (and I'm odd)"
## [1] "I'm step 10 / 10 (and I'm even)"
# A while
i < -10
while (i > 0) {
  print(paste("I'm step", i, "/", 10))
  i <- i - 1
}
## [1] "I'm step 10 / 10"
## [1] "I'm step 9 / 10"
## [1] "I'm step 8 / 10"
## [1] "I'm step 7 / 10"
## [1] "I'm step 6 / 10"
## [1] "I'm step 5 / 10"
## [1] "I'm step 4 / 10"
## [1] "I'm step 3 / 10"
## [1] "I'm step 2 / 10"
## [1] "I'm step 1 / 10"
```

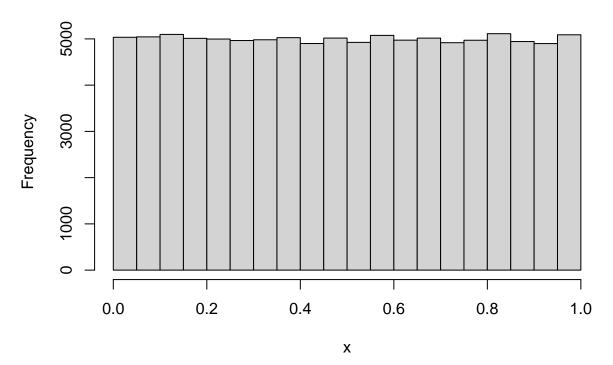

- 5. R has a very nice set of pseudo random number generation functions. In general, distribution functions have the following name structure:
 - a. Random Number Generation: r[name-of-the-distribution], e.g. rnorm for normal, runif for uniform.
 - b. Density function: d[name-of-the-distribution], e.g. dnorm for normal, dunif for uniform.
 - c. Cumulative Distribution Function (CDF): p[name-of-the-distribution], e.g. pnorm for normal, punif for uniform.
 - d. Inverse (quantile) function: q[name-of-the-distribution], e.g. qnorm for the normal, qunif for the uniform.

Here are some examples:

```
# To ensure reproducibility
set.seed(1231)

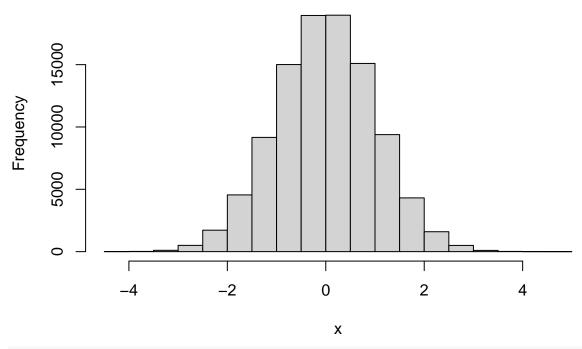

# 100,000 Unif(0,1) numbers
x <- runif(1e5)
hist(x)</pre>
```

Histogram of x

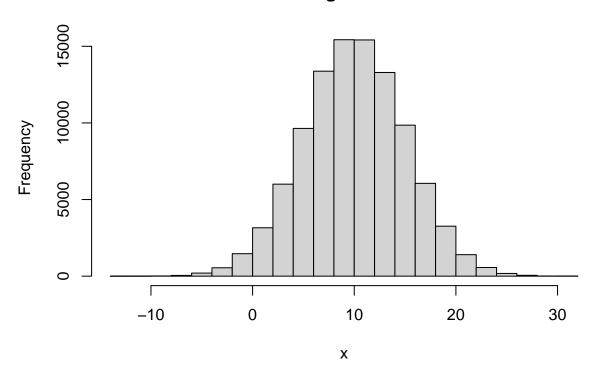

```
# 100,000 N(0,1) numbers
x <- rnorm(1e5)
hist(x)</pre>
```

Histogram of x

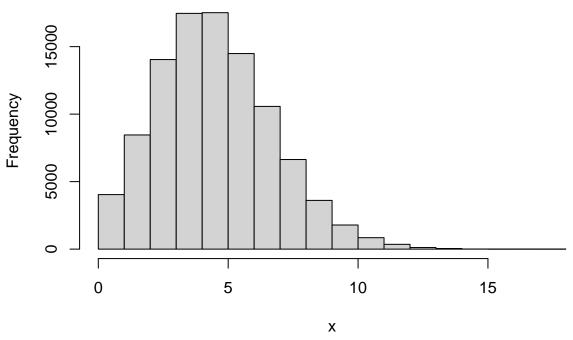

100,000 N(10,25) numbers
x <- rnorm(1e5, mean = 10, sd = 5)
hist(x)</pre>

Histogram of x

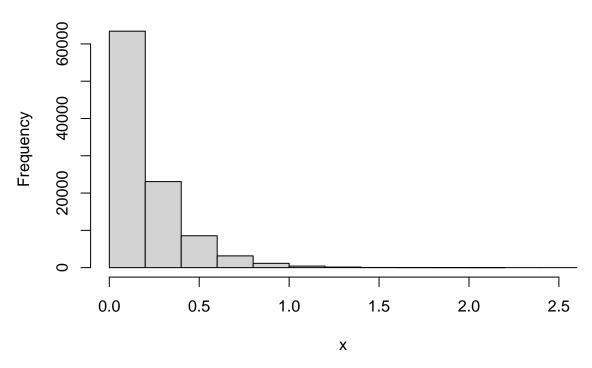

```
# 100,000 Poisson(5) numbers
x <- rpois(1e5, lambda = 5)
hist(x)</pre>
```

Histogram of x

```
# 100,000 rexp(5) numbers
x <- rexp(1e5, 5)
hist(x)</pre>
```

Histogram of x

More distributions available at ??Distributions.

For a nice intro to R, take a look at "The Art of R Programming" by Norman Matloff. For more advanced users, take a look at "Advanced R" by Hadley Wickham.

For this book, we need the following

R Core Team (2017b)

- Install R from CRAN: https://www.r-project.org/
- 2. (optional) Install Rstudio: https://rstudio.org

While I find RStudio extremely useful, it is not necessary to use it with R.

Chapter 4

Network Nomination Data

You can download the data for this chapter here.

The codebook for the data provided here is in the appendix.

The goals for this chapter are:

- 1. Read the data into R,
- 2. Create a network with it,
- 3. Compute descriptive statistics
- 4. Visualize the network

4.1 Data preprocessing

4.1.1 Reading the data into R

R has several ways of reading data. Your data can be Raw plain files like CSV, tab-delimited, or specified by column width. To read plain-text data, you can use the readr package (Wickham, Hester, and Francois 2017). In the case of binary files, like Stata, Octave, or SPSS files, you can use the R package foreign (R Core Team 2017a). If your data is formatted as Microsoft spreadsheets, the readxl R package (Wickham and Bryan 2017) is the alternative to use. In our case, the data for this session is in Stata format:

```
library(foreign)

# Reading the data
dat <- foreign::read.dta("03-sns.dta")

# Taking a look at the data's first 5 columns and 5 rows
dat[1:5, 1:10]</pre>
```

4.1.2 Creating a unique id for each participant

Now suppose that we want to create a unique id using the school and photo id. In this case, since both variables are numeric, a good way of doing it is to encode the id. For example, the last three numbers are the photoid and the first ones are the school id. To do this, we need to take into account the range of the variables:

```
(photo_id_ran <- range(dat$photoid))
## [1] 1 2074</pre>
```

As the variable spans up to 2074, we need to set the last 4 units of the variable to store the photoid. We will use dplyr (Wickham et al. 2017) and magrittr (Bache and Wickham 2014)] (the pipe operator, %>%) to create this variable, and we will call it... id (mind blowing, right?):

```
library(dplyr)
```

```
##
## Attaching package: 'dplyr'
## The following objects are masked from 'package:stats':
##
## filter, lag
## The following objects are masked from 'package:base':
##
## intersect, setdiff, setequal, union

library(magrittr)

(dat %<>% mutate(id = school*10000 + photoid)) %>%
head %>%
select(school, photoid, id)
```

```
## 1
        111
                   1 1110001
## 2
        111
                   2 1110002
## 3
        111
                   7 1110007
## 4
        111
                  13 1110013
## 5
        111
                  14 1110014
## 6
        111
                  15 1110015
```

Wow, what happened in the last three lines of code! What is that %>%? Well, that's the pipe operator, and it is an appealing way of writing nested function calls. In this case, instead of writing something like:

```
dat_filtered$id <- dat_filtered$school*10000 + dat_filtered$photoid
subset(head(dat_filtered), select = c(school, photoid, id))</pre>
```

4.2 Creating a network

- We want to build a social network. For that, we either use an adjacency matrix or an edgelist.
- Each individual of the SNS data nominated 19 friends from school. We will use those nominations to create the social network.
- In this case, we will create the network by coercing the dataset into an edgelist.

4.2.1 From survey to edgelist

Let's start by loading a couple of handy R packages. We will load tidyr (Wickham and Henry 2017) and stringr (Wickham 2017). We will use the first, tidyr, to reshape the data. The second, stringr, will help us processing strings using regular expressions¹.

```
library(tidyr)
library(stringr)
```

Optionally, we can use the tibble type of object, which is an alternative to the actual data.frame. This object is said to provide *more efficient methods for matrices and data frames*.

```
dat <- as_tibble(dat)</pre>
```

What I like from tibbles is that when you print them on the console, these actually look nice:

```
dat
```

```
## # A tibble: 2,164 x 100
## photoid school hispanic female1 female2 female3 female4 grades1 grades2
```

¹Please refer to the help file?'regular expression' in R. The R package rex (Ushey, Hester, and Krzyzanowski 2017) is a very nice companion for writing regular expressions. There's also a neat (but experimental) RStudio add-in that can be very helpful for understanding how regular expressions work, the regexplain add-in.

```
<int> <int>
                         <dbl>
                                 <int>
                                         <int>
                                                  <int>
                                                          <int>
                                                                   <dbl>
                                                                           <dbl>

```

Maybe too much piping... but its cool!
net <- dat %>%

```
select(id, school, starts_with("sch_friend")) %>%
gather(key = "varname", value = "content", -id, -school) %>%
filter(!is.na(content)) %>%
mutate(
  friendid = school*10000 + content,
  year = as.integer(str_extract(varname, "(?<=[a-z])[0-9]")),
  nnom = as.integer(str_extract(varname, "(?<=[a-z][0-9])[0-9]+"))
)</pre>
```

Let's take a look at this step by step:

1. First, we subset the data: We want to keep id, school, sch_friend*. For the later, we use the function starts_with (from the tidyselect package). The latter allows us to select all variables that start with the word "sch_friend", which means that sch_friend11, sch_friend12, ... will be selected.

```
dat %>%
  select(id, school, starts_with("sch_friend"))
```

```
## # A tibble: 2.164 x 78
##
           id school sch_friend11 sch_friend12 sch_friend13 sch_friend14

```

2. Then, we reshape it to *long* format: By transposing all the sch_friend* to long format. We do this using the function gather (from the tidyr package); an alternative to the reshape function, which I find easier to use. Let's see how it works:

```
dat %>%
  select(id, school, starts_with("sch_friend")) %>%
  gather(key = "varname", value = "content", -id, -school)
```

```
## # A tibble: 164,464 x 4
##
           id school varname
                                  content
        <dbl> <int> <chr>
##
                                    <int>
## 1 1110001
                 111 sch_friend11
                                       NA

                 111 sch_friend11
## 8 1110022
                                      NA
## 9 1110025
                 111 sch_friend11
                                      135
## 10 1110027
                 111 sch_friend11
                                      346
## # ... with 164,454 more rows
```

In this case, the key parameter sets the name of the variable that will contain the name of the variable that was reshaped, while value is the name of the variable that will hold the content of the data (that's why I named those like that). The -id, -school bit tells the function to "drop" those variables before reshaping. In other words, "reshape everything but id and school."

Also, notice that we passed from 2164 rows to 19 (nominations) * 2164 (subjects) * 4 (waves) = 164464 rows, as expected.

3. As the nomination data can be empty for some cells, we need to take care of those cases, the NAs, so we filter the data:

... with 39,551 more rows

```
dat %>%
  select(id, school, starts_with("sch_friend")) %>%
  gather(key = "varname", value = "content", -id, -school) %>%
  filter(!is.na(content))
## # A tibble: 39,561 x 4
##
           id school varname
                                  content
        <dbl> <int> <chr>
##
                                    <int>
## 1 1110002
                 111 sch_friend11

                                      462
```

4. And finally, we create three new variables from this dataset: friendid,, year, and nom_num (nomination number). All using regular expressions:

```
dat %>%
  select(id, school, starts_with("sch_friend")) %>%
  gather(key = "varname", value = "content", -id, -school) %>%
  filter(!is.na(content)) %>%
  mutate(
    friendid = school*10000 + content,
    year = as.integer(str_extract(varname, "(?<=[a-z])[0-9]")),
    nnom = as.integer(str_extract(varname, "(?<=[a-z][0-9])[0-9]+"))
    )</pre>
```

```
## # A tibble: 39,561 x 7
           id school varname
##
                                 content friendid year nnom
##
       <dbl> <int> <chr>
                                   <int>
                                            <dbl> <int> <int>
   1 1110002
                111 sch friend11
                                     424 1110424
                                                      1

                                                            1
## 8 1110027
                111 sch_friend11
                                     346 1110346
                                                      1
                                                            1
## 9 1110029
                111 sch_friend11
                                     369 1110369
                                                      1
                                                            1
```

The regular expression (?<=[a-z]) matches a string preceded by any letter from a to z. In contrast, the expression [0-9] matches a single number. Hence, from the string "sch_friend12", the regular expression will only match the 1, as it is the only number followed by a letter. The expression (?<=[a-z][0-9]) matches a string preceded by a lower case letter and a one-digit number. Finally, the expression [0-9]+ matches a string of numbers—so it could be more than one. Hence, from the string "sch_friend12", we will get 2:

```
str_extract("sch_friend12", "(?<=[a-z])[0-9]")

## [1] "1"

str_extract("sch_friend12", "(?<=[a-z][0-9])[0-9]+")

## [1] "2"</pre>
```

And finally, the as.integer function coerces the returning value from the str_extract function from character to integer. Now that we have this edgelist, we can create an igraph object

4.2.2 igraph network

For coercing the edgelist into an igraph object, we will be using the graph_from_data_frame function in igraph (Csardi and Nepusz 2006). This function receives the following arguments: a data frame where the two first columns are "source" (ego) and "target" (alter), an indicator of whether the network is directed or not, and an optional data frame with vertices, in which's first column should contain the vertex ids.

Using the optional vertices argument is a good practice since, by doing so, you are telling the function what ids that you are expecting to find. Using the original dataset, we will create a data frame name vertices:

```
vertex_attrs <- dat %>%
select(id, school, hispanic, female1, starts_with("eversmk"))
```

Now, let's now use the function graph_from_data_frame to create an igraph object:

```
library(igraph)

ig_year1 <- net %>%
  filter(year == "1") %>%
  select(id, friendid, nnom) %>%
  graph_from_data_frame(
    vertices = vertex_attrs
)
```

Error in graph_from_data_frame(., vertices = vertex_attrs): Some vertex names in edge l

Ups! It seems that individuals are making nominations to other students not included in the survey. How to solve that? Well, it all depends on what you need to do! In this case, we will go for the *quietly-remove-em'-and-don't-tell* strategy:

```
ig_yearl <- net %>%
filter(year == "1") %>%

# Extra line, all nominations must be in ego too.
filter(friendid %in% id) %>%

select(id, friendid, nnom) %>%
graph_from_data_frame(
   vertices = vertex_attrs
   )

ig_yearl
```

```
## IGRAPH 71220e9 DN-- 2164 9514 --

## [21] 1110086->1110206 1110093->1110040 1110094->1110483 1110095->1110043
## + ... omitted several edges
```

So there we have our network with 2164 nodes and 9514 edges. The following steps: get some descriptive stats and visualize our network.

4.3 Network descriptive stats

While we could do all networks at once, in this part, we will focus on computing some network statistics for one of the schools only. We start by school 111. The first question that you should be asking yourself now is, "how can I get that information from the igraph object?." Vertex and edges attributes can be accessed via the V and E functions, respectively; moreover, we can list what vertex/edge attributes are available:

```
list.vertex.attributes(ig_year1)
## [1] "name" "school" "hispanic" "female1" "eversmk1" "eversmk2" "eversmk3"
```

```
## [8] "eversmk4"
```

```
list.edge.attributes(ig_year1)
```

```
## [1] "nnom"
```

Just like we would do with data frames, accessing vertex attributes is done via the dollar sign operator \$. Together with the V function; for example, accessing the first ten elements of the variable hispanic can be done as follows:

```
V(ig_year1)$hispanic[1:10]
```

```
## [1] 1 1 0 1 1 1 1 1 0 1
```

Now that you know how to access vertex attributes, we can get the network corresponding to school 111 by identifying which vertices are part of it and pass that information to the induced_subgraph function:

```
# Which ids are from school 111?
schoollllids <- which(V(ig_year1)$school == 111)

# Creating a subgraph
ig_year1_111 <- induced_subgraph(
    graph = ig_year1,
    vids = schoollllids
)</pre>
```

The which function in R returns a vector of indices indicating which elements pass the test, returning true and false, otherwise. In our case, it will result in a vector of indices of the vertices which have the attribute school equal to 111. With the subgraph, we can compute different centrality measures² for each vertex and store them in the igraph object itself:

```
# Computing centrality measures for each vertex
V(ig_yearl_111)$indegree <- degree(ig_yearl_111, mode = "in")
V(ig_yearl_111)$outdegree <- degree(ig_yearl_111, mode = "out")
V(ig_yearl_111)$closeness <- closeness(ig_yearl_111, mode = "total")
## Warning in closeness(ig_yearl_111, mode = "total"): At centrality.c:
## 2784 :closeness centrality is not well-defined for disconnected graphs
V(ig_yearl_111)$betweeness <- betweenness(ig_yearl_111, normalized = TRUE)</pre>
```

From here, we can *go back* to our old habits and get the set of vertex attributes as a data frame so we can compute some summary statistics on the centrality measurements that we just got

```
# Extracting each vectex features as a data.frame
stats <- as_data_frame(ig_year1_111, what = "vertices")</pre>
```

²For more information about the different centrality measurements, please take a look at the "Centrality" article on Wikipedia.

```
# Computing quantiles for each variable
stats_degree <- with(stats, {
    cbind(
        indegree = quantile(indegree, c(.025, .5, .975)),
        outdegree = quantile(outdegree, c(.025, .5, .975)),
        closeness = quantile(closeness, c(.025, .5, .975)),
        betweeness = quantile(betweeness, c(.025, .5, .975))
)
stats_degree</pre>
```

```
## indegree outdegree closeness betweeness

## 2.5% 0 0 3.526640e-06 0.000000000

## 50% 4 4 1.595431e-05 0.001879006

## 97.5% 16 16 1.601822e-05 0.016591048
```

The with function is somewhat similar to what dplyr allows us to do when we want to work with the dataset but without mentioning its name everytime that we ask for a variable. Without using the with function, the previous could have been done as follows:

```
stats_degree <-
cbind(
  indegree = quantile(stats$indegree, c(.025, .5, .975)),
  outdegree = quantile(stats$outdegree, c(.025, .5, .975)),
  closeness = quantile(stats$closeness, c(.025, .5, .975)),
  betweeness = quantile(stats$betweeness, c(.025, .5, .975))
)</pre>
```

Now we will compute some statistics at the graph level:

```
cbind(
    size = vcount(ig_yearl_111),
    nedges = ecount(ig_yearl_111),
    density = edge_density(ig_yearl_111),
    recip = reciprocity(ig_yearl_111),
    centr = centr_betw(ig_yearl_111)$centralization,
    pathLen = mean_distance(ig_yearl_111)
)
```

```
## size nedges density recip centr pathLen
## [1,] 533 2638 0.009303277 0.3731513 0.02179154 4.23678
```

Triadic census

```
triadic <- triad_census(ig_yearl_111)
triadic</pre>
```

##	[1] 24	1059676	724389	290849	3619	3383	4401	3219	2997
##	[9]	407	33	836	235	163	137	277	85

To get a nicer view of this, we can use a table that I retrieved from $?triad_census$. Moreover, we can normalize the triadic object by its sum instead of looking at raw counts. That way, we get proportions instead³

```
knitr::kable(cbind(
  Pcent = triadic/sum(triadic)*100,
  read.csv("triadic_census.csv")
), digits = 2)
```

Pcent	code	description
95.88	003	A,B,C, the empty graph.
2.89	012	A->B, C, the graph with a single directed edge.
1.16	102	A<->B, C, the graph with a mutual connection between two vertices.
0.01	021D	A<-B->C, the out-star.
0.01	021U	A->B<-C, the in-star.
0.02	021C	A->B->C, directed line.
0.01	111D	A<->B<-C.
0.01	111U	A<->B->C.
0.00	030T	A->B<-C, A->C.
0.00	030C	A<-B<-C, A->C.
0.00	201	A<->B<->C.
0.00	120D	A<-B->C, A<->C.
0.00	120U	A->B<-C, A<->C.
0.00	120C	A->B->C, A<->C.
0.00	210	A->B<->C, A<->C.
0.00	300	A<->B<->C, A<->C, the complete graph.

4.4 Plotting the network in igraph

4.4.1 Single plot

Let's take a look at how does our network looks like when we use the default parameters in the plot method of the igraph object:

```
plot(ig_year1)
```

Not very nice, right? A couple of things with this plot:

1. We are looking at all schools simultaneously, which does not make sense. So, instead of plotting ig_year1, we will focus on ig_year1_111.

³During our workshop, Prof. De la Haye suggested using $\binom{n}{3}$ as a normalizing constant. It turns out that sum(triadic) = choose(n, 3)! So either approach is correct.

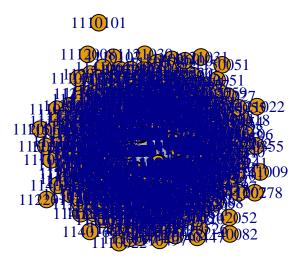

Figure 4.1: A not very nice network plot. This is what we get with the default parameters in igraph.

- 2. All the vertices have the same size and are overlapping. Instead of using the default size, we will size the vertices by indegree using the degree function and passing the vector of degrees to vertex.size.⁴
- 3. Given the number of vertices in these networks, the labels are not useful here. So we will remove them by setting vertex.label = NA. Moreover, we will reduce the size of the arrows' tip by setting edge.arrow.size = 0.25.
- 4. And finally, we will set the color of each vertex to be a function of whether the individual is Hispanic or not. For this last bit we need to go a bit more of programming:

```
col_hispanic <- V(ig_year1_111)$hispanic + 1
col_hispanic <- coalesce(col_hispanic, 3)
col_hispanic <- c("steelblue", "tomato", "white")[col_hispanic]</pre>
```

Line by line, we did the following:

- 1. The first line added one to all no NA values so that the 0s (non-Hispanic) turned to 1s and the 1s (Hispanic) turned to 2s.
- 2. The second line replaced all NAs with the number three so that our vector col_hispanic now ranges from one to three with no NAs in it.
- 3. In the last line, we created a vector of colors. Essentially, what we are doing here is telling R to create a vector of length length(col_hispanic) by selecting elements by index from the vector c("steelblue", "tomato", "white"). This way, if, for example, the first element of the vector col_hispanic was a 3, our new vector of colors would have a "white" in it.

⁴Figuring out what is the optimal vertex size is a bit tricky. Without getting too technical, there's no other way of getting *nice* vertex size other than just playing with different values of it. A nice solution to this is using netdiffuseR::igraph_vertex_rescale which rescales the vertices so that these keep their aspect ratio to a predefined proportion of the screen.

To make sure we know we are right, let's print the first 10 elements of our new vector of colors together with the original hispanic column:

```
cbind(
  original = V(ig_year1_111)$hispanic[1:10],
  colors = col_hispanic[1:10]
)
```

```
##
         original colors
    [1,] "1"
                  "tomato"
##
    [2,] "1"
##
                  "tomato"
    [3,] "0"
                  "steelblue"
##
                  "tomato"
## [4,] "1"
## [5,] "1"
                  "tomato"
## [6,] "1"
                  "tomato"
## [7,] "1"
                  "tomato"
                  "tomato"
## [8,] "1"
## [9,] "0"
                  "steelblue"
                  "tomato"
## [10,] "1"
```

With our nice vector of colors, now we can pass it to plot.igraph (which we call implicitly by just calling plot), via the vertex.color argument:

```
# Fancy graph
set.seed(1)
plot(
   ig_yearl_111,
   vertex.size = degree(ig_yearl_111)/10 +1,
   vertex.label = NA,
   edge.arrow.size = .25,
   vertex.color = col_hispanic
)
```

Nice! So it does look better. The only problem is that we have a lot of isolates. Let's try again by drawing the same plot without isolates. To do so, we need to filter the graph, for which we will use the function induced_subgraph

```
# Which vertices are not isolates?
which_ids <- which(degree(ig_yearl_111, mode = "total") > 0)

# Getting the subgraph
ig_yearl_111_sub <- induced_subgraph(ig_yearl_111, which_ids)

# We need to get the same subset in col_hispanic
col_hispanic <- col_hispanic[which_ids]</pre>
```

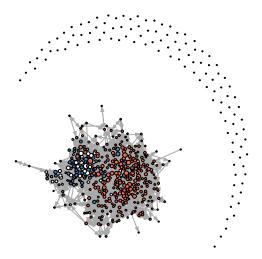

Figure 4.2: Friends network in time 1 for school 111.

```
# Fancy graph
set.seed(1)
plot(
   ig_year1_111_sub,
   vertex.size = degree(ig_year1_111_sub)/5 +1,
   vertex.label = NA,
   edge.arrow.size = .25,
   vertex.color = col_hispanic
)
```

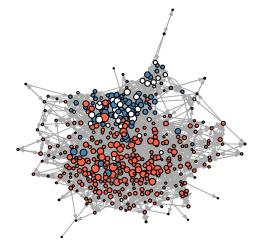

Figure 4.3: Friends network in time 1 for school 111. The graph excludes isolates.

Now that's better! An interesting pattern that shows up is that individuals seem to cluster by whether they are Hispanic or not.

We can write this as a function to avoid copying and pasting the code n times (supposing that we want to create a plot similar to this n times). We do the latter in the following subsection.

4.4.2 Multiple plots

When you are repeating yourself repeatedly, it is a good idea to write down a sequence of commands as a function. In this case, since we will be running the same type of plot for all schools/waves, we write a function in which the only things that change are: (a) the school id, and (b) the color of the nodes.

```
myplot <- function(</pre>
  net,
  schoolid,
  mindgr = 1,
  vcol = "tomato",
  ...) {
  # Creating a subgraph
  subnet <- induced_subgraph(</pre>
    net,
    which(degree(net, mode = "all") >= mindgr & V(net)$school == schoolid)
  )
  # Fancy graph
  set.seed(1)
  plot(
    subnet,
    vertex.size
                    = degree(subnet)/5,
    vertex.label = NA,
    edge.arrow.size = .25,
    vertex.color = vcol,
    . . .
}
```

The function definition:

- 1. The myplot <- function([arguments]) {[body of the function]} tells R that we are going to create a function called myplot.
- 2. We declare four specific arguments: net, schoolid, mindgr, and vcol. These are an igraph object, the school id, the minimum degree that vertices must have to be included in the figure, and the color of the vertices. Observe that, compared to other programming languages, R does not require declaring the data types.
- 3. The ellipsis object, ..., is an especial object in R that allows us to pass other arguments without specifying which. If you take a look at the plot bit in the function body, you will see that we also added We use the ellipsis to pass extra arguments (different from the ones that we explicitly defined) directly to plot. In practice, this implies that we can,

for example, set the argument edge.arrow.size when calling myplot, even though we did not include it in the function definition! (See ?dotsMethods in R for more details).

In the following lines of code, using our new function, we will plot each schools' network in the same plotting device (window) with the help of the par function, and add legend with the legend:

```
# Plotting all together
oldpar <- par(no.readonly = TRUE)</pre>
par(mfrow = c(2, 3), mai = rep(0, 4), oma = c(1, 0, 0, 0))
myplot(ig_year1, 111, vcol = "tomato")
myplot(ig_year1, 112, vcol = "steelblue")
myplot(ig_year1, 113, vcol = "black")
myplot(ig_year1, 114, vcol = "gold")
myplot(ig_year1, 115, vcol = "white")
par(oldpar)
# A fancy legend
legend(
  "bottomright",
  legend = c(111, 112, 113, 114, 115),
  pt.bg = c("tomato", "steelblue", "black", "gold", "white"),
  pch
        = 21,
  cex
        = 1,
       = "n",
  bty
  title = "School"
```

So what happened here?

- oldpar <- par(no.readonly = TRUE) This line stores the current parameters for plotting. Since we are going to be changing them, we better make sure we are able to go back!.
- par(mfrow = c(2, 3), mai = rep(0, 4), oma=rep(0, 4)) Here we are setting various things at the same time. mfrow specifies how many figures will be drawn, and in what order. In particular, we are asking the plotting device to make room for 2*3 = 6 figures organized in two rows and three columns drawn by row.

mai specifies the size of the margins in inches, setting all margins equal to zero (which is what we are doing now) gives more space to the graph. The same is true for oma. See ?par for more info.

- myplot(ig_year1, ...) This is simply calling our plotting function. The neat part of this is that, since we set mfrow = c(2, 3), R takes care of *distributing* the plots in the device.
- par(oldpar) This line allows us to restore the plotting parameters.

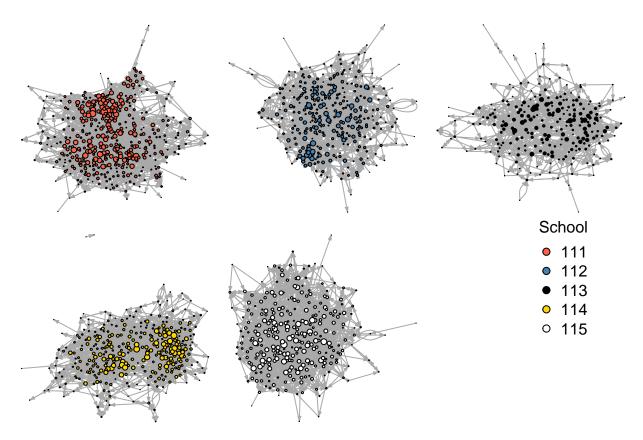

Figure 4.4: All 5 schools in time 1. Again, the graphs exclude isolates.

4.5 Statistical tests

4.5.1 Is nomination number correlated with indegree?

Hypothesis: Individuals that, on average, are among the first nominations of their peers are more popular

```
# Getting all the data in long format
edgelist <- as_long_data_frame(ig_year1) %>%
    as_tibble

# Computing indegree (again) and average nomination number
# Include "On a scale from one to five how close do you feel"
# Also for egocentric friends (A. Friends)
indeg_nom_cor <- group_by(edgelist, to, to_name, to_school) %>%
    summarise(
    indeg = length(nnom),
    nom_avg = l/mean(nnom)
) %>%
    rename(
    school = to_school
```

```
)
indeg_nom_cor
## # A tibble: 1,561 x 5
## # Groups: to, to_name [1,561]
         to to_name school indeg nom_avg
##
##
      <dbl> <chr>
                     <int> <int>
                                   <dbl>
##
   1

Exponential Random Graph Models

I strongly suggest reading the vignette included in the ergm R package

vignette("ergm", package="ergm")

The purpose of ERGMs, in a nutshell, is to describe parsimoniously the local selection forces that shape the global structure of a network. To this end, a network dataset, like those depicted in Figure 1, may be considered as the response in a regression model, where the predictors are things like "propensity for individuals of the same sex to form partnerships" or "propensity for individuals to form triangles of partnerships". In Figure 1(b), for example, it is evident that the individual nodes appear to cluster in groups of the same numerical labels (which turn out to be students' grades, 7 through 12); thus, an ERGM can help us quantify the strength of this intra-group effect.

— (David R. Hunter et al. 2008)

In a nutshell, we use ERGMs as a parametric interpretation of the distribution of **Y**, which takes the canonical form:

$$\Pr(\mathbf{Y} = \mathbf{y} | \theta, \mathcal{Y}) = \frac{\exp\left\{\theta^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}}{\kappa(\theta, \mathcal{Y})}, \quad \mathbf{y} \in \mathcal{Y}$$

Where $\theta \in \Omega \subset \mathbb{R}^q$ is the vector of model coefficients and $\mathbf{g}(\mathbf{y})$ is a q-vector of statistics based on the adjacency matrix \mathbf{y} .

Model (5) may be expanded by replacing g(y) with g(y, X) to allow for additional covariate information X about the network. The denominator,

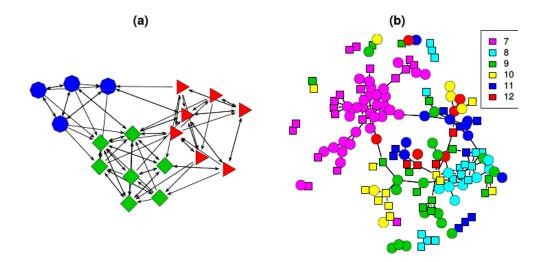

Figure 1: The (a) samplike and (b) faux.mesa.high networks described in Section 2. The values of nodal covariates may be indicated using various colors, shapes, and labels of nodes.

Figure 5.1: Source: Hunter et al. (2008)

$$\kappa(\boldsymbol{\theta}, \mathcal{Y}) = \sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\boldsymbol{\theta}^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}$$

,is the normalizing factor that ensures that equation (5) is a legitimate probability distribution. Even after fixing \mathcal{Y} to be all the networks that have size n, the size of \mathcal{Y} makes this type of statistical model hard to estimate as there are $N=2^{n(n-1)}$ possible networks! (David R. Hunter et al. 2008)

Recent developments include new forms of dependency structures to take into account more general neighborhood effects. These models relax the one-step Markovian dependence assumptions, allowing investigation of longer-range configurations, such as longer paths in the network or larger cycles (Pattison and Robins 2002). Models for bipartite (Faust and Skvoretz 1999) and tripartite (Mische and Robins 2000) network structures have been developed. (David R. Hunter et al. 2008, 9)

5.1 A naïve example

In the simplest case, ergm is equivalent to a logistic regression

5.2 Estimation of ERGMs

The ultimate goal is to perform statistical inference on the proposed model. In a *standard* setting, we would be able to use Maximum-Likelihood-Estimation (MLE), which consists of finding the model parameters θ that, given the observed data, maximize the likelihood of the model. For the latter, we generally use Newton's method. Newton's method requires been able to compute the log-likelihood of the model, which in ERGMs can be challenging.

For ERGMs, since part of the likelihood involves a normalizing constant that is a function of all possible networks, this is not as straightforward as in the regular setting. Because of it, most estimation methods rely on simulations.

In statnet, the default estimation method is based on a method proposed by (Geyer and Thompson 1992), Markov-Chain MLE, which uses Markov-Chain Monte Carlo for simulating networks and a modified version of the Newton-Raphson algorithm to estimate the parameters.

The idea of MC-MLE for this family of statistical models is that we can approximate the expectation of normalizing constant ratios using the law of large numbers. In particular, the following:

$$\frac{\kappa(\theta, \mathcal{Y})}{\kappa(\theta_0, \mathcal{Y})} = \frac{\sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\theta^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}}{\sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\theta^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}}$$

$$= \sum_{\mathbf{y} \in \mathcal{Y}} \left(\frac{1}{\sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\theta^{\mathsf{T}}_{0} \mathbf{g}(\mathbf{y})\right\}} \times \exp\left\{\theta^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}\right)$$

$$= \sum_{\mathbf{y} \in \mathcal{Y}} \left(\frac{\exp\left\{\theta^{\mathsf{T}}_{0} \mathbf{g}(\mathbf{y})\right\}}{\sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\theta^{\mathsf{T}}_{0} \mathbf{g}(\mathbf{y})\right\}} \times \exp\left\{(\theta - \theta_{0})^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}\right)$$

$$= \sum_{\mathbf{y} \in \mathcal{Y}} \left(\Pr(Y = y | \mathcal{Y}, \theta_{0}) \times \exp\left\{(\theta - \theta_{0})^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}\right)$$

$$= E_{\theta_{0}} \left(\exp\left\{(\theta - \theta_{0})^{\mathsf{T}} \mathbf{g}(\mathbf{y})\right\}\right)$$

In particular, the MC-MLE algorithm uses this fact to maximize the ratio of log-likelihoods. The objective function itself can be approximated by simulating m networks from the distribution with parameter θ_0 :

$$l(\theta) - l(\theta_0) \approx (\theta - \theta_0)^{\mathsf{T}} \mathbf{g}(\mathbf{y}_{obs}) - \log \left[\frac{1}{m} \sum_{i=1}^{m} \exp\left\{ (\theta - \theta_0)^{\mathsf{T}} \right\} \mathbf{g}(\mathbf{Y}_i) \right]$$

For more details, see (David R. Hunter et al. 2008). A sketch of the algorithm follows:

- 1. Initialize the algorithm with an initial guess of θ , call it $\theta^{(t)}$ (must be a rather OK guess)
- 2. While (no convergence) do:
 - a. Using $\theta^{(t)}$, simulate M networks by means of small changes in the \mathbf{Y}_{obs} (the observed network). This part is done by using an importance-sampling method which weights each proposed network by it's likelihood conditional on $\theta^{(t)}$
 - b. With the networks simulated, we can do the Newton step to update the parameter $\theta^{(t)}$ (this is the iteration part in the ergm package): $\theta^{(t)} \to \theta^{(t+1)}$.
 - c. If convergence has been reached (which usually means that $\theta^{(t)}$ and $\theta^{(t+1)}$ are not very different), then stop; otherwise, go to step a.

For more details see (Lusher, Koskinen, and Robins 2012; Admiraal and Handcock 2006; Snijders 2002; Wang et al. 2009) provides details on the algorithm used by PNet (which is the same as the one used in RSiena). (Lusher, Koskinen, and Robins 2012) provides a short discussion on differences between ergm and PNet.

5.3 The ergm package

The ergm R package (Handcock et al. 2017)

From the previous section:¹

```
library(igraph)
library(magrittr)
library(dplyr)
load("03.rda")
```

In this section we will use the ergm package (from the statnet suit of packages (Handcock et al. 2016)) suit, and the intergraph (Bojanowski 2015) package. The latter provides functions to go back and forth between igraph and network objects from the igraph and network packages respectively²

```
library(ergm)
library(intergraph)
```

As a rather important side note, the order in which R packages are loaded matters. Why is this important to mention now? Well, it turns out that at least a couple of functions in the network package have the same name of some functions in the igraph package. When the ergm package is loaded, since it depends on network, it will load the network package first, which will *mask* some functions in igraph. This becomes evident once you load ergm after loading igraph:

¹You can download the 03.rda file from this link.

²Yes, the classes have the same name as the packages.

The following objects are masked from 'package:igraph':

```
add.edges, add.vertices, %c%, delete.edges, delete.vertices, get.edge.attribute, get.edg get.vertex.attribute, is.bipartite, is.directed, list.edge.attributes, list.vertex.attribute set.edge.attribute, set.vertex.attribute
```

What are the implications of this? If you call the function list.edge.attributes for an object of class igraph R will return an error as the first function that matches that name comes from the network package! To avoid this you can use the double colon notation:

```
igraph::list.edge.attributes(my_igraph_object)
network::list.edge.attributes(my_network_object)
```

Anyway... Using the asNetwork function, we can coerce the igraph object into a network object so we can use it with the ergm function:

```
# Creating the new network
network_111 <- intergraph::asNetwork(ig_year1_111)</pre>
# Running a simple ergm (only fitting edge count)
ergm(network_111 ~ edges)
## [1] "Warning: This network contains loops"
## [1] "Warning: This network contains loops"
## Starting maximum pseudolikelihood estimation (MPLE):
## Evaluating the predictor and response matrix.
## Maximizing the pseudolikelihood.
## Finished MPLE.
## Stopping at the initial estimate.
## Evaluating log-likelihood at the estimate.
##
## MLE Coefficients:
## edges
## -4.734
```

So what happened here! We got a warning. It turns out that our network has loops (didn't thought about it before!). Let's take a look at that with the which_loop function

```
E(ig_year1_111)[which_loop(ig_year1_111)]
```

```
## + 1/2638 edge from 6f34d4e (vertex names):
## [1] 1110111->1110111
```

We can get rid of these using the igraph::-.igraph. Let's remove the isolates using the same operator

```
# Creating the new network
network_111 <- ig_year1_111

# Removing loops
network_111 <- network_111 - E(network_111)[which(which_loop(network_111))]

# Removing isolates
network_111 <- network_111 - which(degree(network_111, mode = "all") == 0)

# Converting the network
network_111 <- intergraph::asNetwork(network_111)</pre>
```

asNetwork(simplify(ig_year1_111)) ig_year1_111 %>% simplify %>% asNetwork

A problem that we have on this data is the fact that some vertices have missing values in the variables hispanic, female1, and eversmk1. For now, we will proceed by imputing values based on the avareges:

```
for (v in c("hispanic", "female1", "eversmk1")) {
  tmpv <- network_111 %v% v
  tmpv[is.na(tmpv)] <- mean(tmpv, na.rm = TRUE) > .5
  network_111 %v% v <- tmpv
}</pre>
```

5.4 Running ERGMs

Proposed workflow:

- 1. Estimate the simplest model, adding one variable at a time.
- 2. After each estimation, run the mcmc.diagnostics function to see how good (or bad) behaved the chains are.
- 3. Run the gof function and verify how good the model matches the network's structural statistics.

What to use:

- 1. control.ergms: Maximum number of iteration, seed for Pseudo-RNG, how many cores
- 2. ergm.constraints: Where to sample the network from. Gives stability and (in some cases) faster convergence as by constraining the model you are reducing the sample size.

Here is an example of a couple of models that we could compare³

³Notice that this document may not include the usual messages that the ergm command generates during the estimation procedure. This is just to make it more printable-friendly.

5.4. RUNNING ERGMS 47

```
ans0 <- ergm(
  network_111 ~
    edges +
    nodematch("hispanic") +
    nodematch("female1") +
    nodematch("eversmk1") +
    mutual
    ,
    constraints = ~bd(maxout = 19),
    control = control.ergm(
        seed = 1,
        MCMLE.maxit = 10,
        parallel = 4,
        CD.maxit = 10
    )
    )
}</pre>
```

```
## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.

## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.
```

So what are we doing here:

- 1. The model is controlling for:
 - a. edges Number of edges in the network (as opposed to its density)
 - b. nodematch("some-variable-name-here") Includes a term that controls for homophily/heterophily
 - c. mutual Number of mutual connections between (i, j), (j, i). This can be related to, for example, triadic closure.

For more on control parameters, see (Morris, Handcock, and Hunter 2008).

```
ans1 <- ergm(
network_111 ~
    edges +
    nodematch("hispanic") +
    nodematch("female1") +
    nodematch("eversmk1")
    ,
    constraints = ~bd(maxout = 19),</pre>
```

```
## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.

## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.
```

This example takes longer to compute

```
ans2 <- ergm(
  network_111 ~
    edges +
    nodematch("hispanic") +
    nodematch("female1") +
    nodematch("eversmk1") +
    mutual +
    balance
  constraints = ~bd(maxout = 19),
  control = control.ergm(
    seed
               = 1,
   MCMLE.maxit = 10,
    parallel = 4,
    CD.maxit
             = 10
```

```
## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.

## Warning in nobs.ergm(object, ...): The number of observed dyads in this
## network is ill-defined due to complex constraints on the sample space.
## Disable this warning with 'options(ergm.loglik.warn_dyads=FALSE)'.
```

Now, a nice trick to see all regressions in the same table, we can use the texreg package

5.4. RUNNING ERGMS 49

(Leifeld 2013) which supports ergm ouputs!

balance

AIC

Or, if you are using rmarkdown, you can export the results using LaTeX or html, let's try the latter to see how it looks like here:

```
texreg(list(ans0, ans1, ans2))
## Warning: This object was fit with 'ergm' version 3.10.4.5075 or earlier.
## Summarizing it with version 3.11 or later may return incorrect results or fail.
## Warning: This object was fit with 'ergm' version 3.10.4.5075 or earlier.
## Summarizing it with version 3.11 or later may return incorrect results or fail.
```

```
## Warning: This object was fit with 'ergm' version 3.10.4.5075 or earlier.
```

Summarizing it with version 3.11 or later may return incorrect results or fail.

5.5 Model Goodness-of-Fit

library(texreg)

In raw terms, once each chain has reach stationary distribution, we can say that there are no problems with autocorrelation and that each sample point is iid. This implies that, since we are running the model with more than 1 chain, we can use all the samples (chains) as a single dataset.

Recent changes in the ergm estimation algorithm mean that these plots can no

longer be used to ensure that the mean statistics from the model match the observed network statistics. For that functionality, please use the GOF command: gof(object, GOF=~model).

```
--?ergm::mcmc.diagnostics
```

Since ans0 is the one model which did best, let's take a look at it's GOF statistics. First, lets see how the MCMC did. For this we can use the mcmc.diagnostics function including in the package. This function is actually a wrapper of a couple of functions from the coda package (Plummer et al. 2006) which is called upon the \$sample object which holds the *centered* statistics from the sampled networks. This last point is important to consider since at first look it can be confusing to look at the \$sample object since it neither matches the observed statistics, nor the coefficients.

When calling the function mcmc.diagnostics(ans0, centered = FALSE), you will see a lot of output including a couple of plots showing the trace and posterior distribution of the *uncentered* statistics (centered = FALSE). In the next code chunks we will reproduce the output from the mcmc.diagnostics function step by step using the coda package. First we need to *uncenter* the sample object:

```
# Getting the centered sample
sample_centered <- ans0$sample</pre>
# Getting the observed statistics and turning it into a matrix so we can add it
# to the samples
observed <- summary(ans0$formula)</pre>
observed <- matrix(</pre>
  observed,
  nrow = nrow(sample_centered[[1]]),
  ncol = length(observed),
  byrow = TRUE
  )
# Now we uncenter the sample
sample_uncentered <- lapply(sample_centered, function(x) {</pre>
  x + observed
})
# We have to make it an mcmc.list object
sample_uncentered <- coda::mcmc.list(sample_uncentered)</pre>
```

Under the hood:

1. Empirical means and sd, and quantiles:

```
summary(sample_uncentered)
```

##

```
## Iterations = 16384:1063936
## Thinning interval = 1024
## Number of chains = 4
## Sample size per chain = 1024
##
## 1. Empirical mean and standard deviation for each variable,
##
      plus standard error of the mean:
##
##
                                SD Naive SE Time-series SE
                        Mean
                      2474.3 55.40
## edges

3. *Autocorrelation*: For now, we will only look at autocorrelation for chain one. Autocorrelation should be small (in a general MCMC setting). If autocorrelation is high, then it means that your sample is not idd (no Markov property). A way out to solve this is *thinning* the sample.

coda::autocorr(sample_uncentered)[[1]]

```

4. Geweke Diagnostic: From the function's help file:

"If the samples are drawn from the stationary distribution of the chain, the two means are equal and Geweke's statistic has an asymptotically standard normal distribution. [...] The Z-score is calculated under the assumption that the two parts of the chain are asymptotically independent, which requires that the sum of frac1 and frac2 be strictly less than 1.""

—?coda::geweke.diag

Let's take a look at a single chain:

```
coda::geweke.diag(sample_uncentered)[[1]]
##
## Fraction in 1st window = 0.1
## Fraction in 2nd window = 0.5
##
##
                edges nodematch.hispanic nodematch.female1 nodematch.eversmk1

                                                                          0.6644
##
               mutual
##
               1.1170
```

5. (not included) Gelman Diagnostic: From the function's help file:

Gelman and Rubin (1992) propose a general approach to monitoring convergence of MCMC output in which m>1 parallel chains are run with starting values that are overdispersed relative to the posterior distribution. Convergence is diagnosed when the chains have 'forgotten' their initial values, and the output from all chains is indistinguishable. The gelman.diag diagnostic is applied to a single variable from the chain. It is based a comparison of within-chain and between-chain variances, and is similar to a classical analysis of variance. —?coda::gelman.diag

As a difference from the previous diagnostic statistic, this uses all chains simulatenously:

```
coda::gelman.diag(sample_uncentered)
```

```

```

As a rule of thumb, values that are in the [.9, 1.1] are good.

One nice feature of the mcmc.diagnostics function is the nice trace and posterior distribution plots that it generates. If you have the R package latticeExtra (Sarkar and Andrews 2016), the function will override the default plots used by coda::plot.mcmc and use lattice instead, creating a nicer looking plots. The next code chunk calls the mcmc.diagnostic function, but we suppress the rest of the output (see figure ??).

mcmc.diagnostics(ans0, center = FALSE) # Suppressing all the output

Sample statistics edges edges $0.000\,0.002\,0.004\,0.006\,0.008$ 2500 2600 nodematch.hispanic nodematch.hispanic 0.008 0.004 0.000 nodematch.female1 nodematch.female1 0.008 0.004 0.000

Figure 5.2: Trace and posterior distribution of sampled network statistics.

If we called the function mcmc.diagnostics, this message appears at the end:

MCMC diagnostics shown here are from the last round of simulation, prior to compu-

Sample statistics

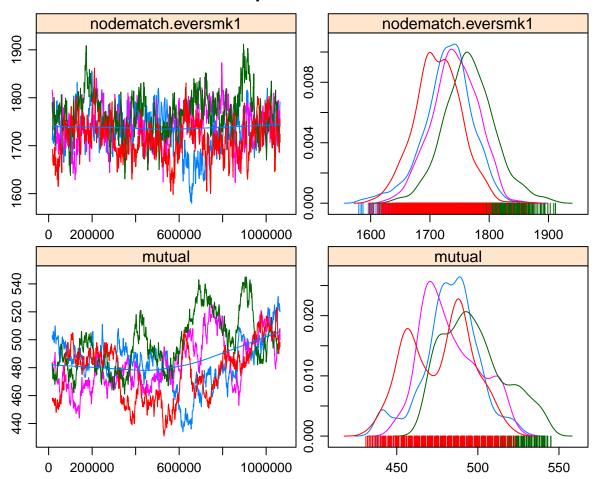

Figure 5.3: Trace and posterior distribution of sampled network statistics (cont'd).

tation of final parameter estimates. Because the final estimates are refinements of those used for this simulation run, these diagnostics may understate model performance. To directly assess the performance of the final model on in-model statistics, please use the GOF command: gof(ergmFitObject, GOF=~model).

—mcmc.diagnostics(ans0)

Not that bad (although the mutual term could do better)!⁴ First, observe that in the figure we see four different lines; why is that? Since we were running in parallel using four cores, the algorithm ran four chains of the MCMC algorithm. An eyeball test is to see if all the chains moved at about the same place; in such a case, we can start thinking about model convergence from the MCMC perspective.

Once we are sure to have reach convergence on the MCMC algorithm, we can start thinking about how well does our model predicts the observed network's proterties. Besides the statistics that define our ERGM, the gof function's default behavior show GOF for:

⁴The statnet wiki website as a very nice example of (very) bad and good MCMC diagnostics plots here.

- a. In degree distribution,
- b. Out degree distribution,
- c. Edge-wise shared partners, and

Computing and printing GOF estatistics

d. Geodesics

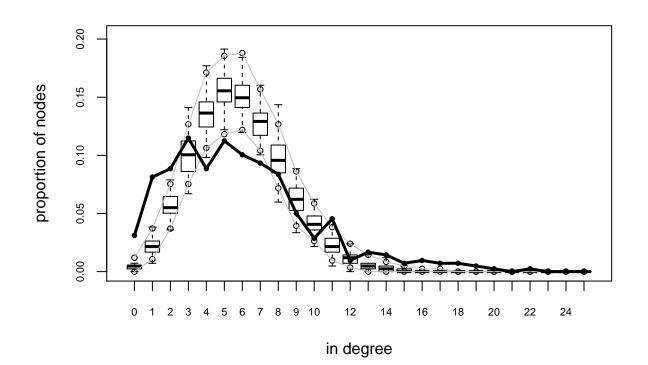

Let's take a look at it

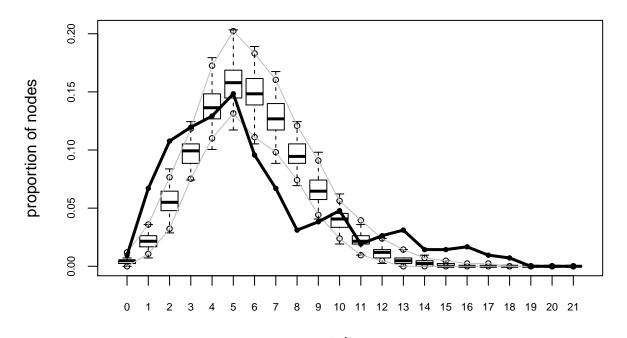

ans_gof <- gof(ans0)</pre>

model statistics

Try the following configuration instead

```
ans0_bis <- ergm(
network_111 ~
  edges +
  nodematch("hispanic") +</pre>
```

Increase the sample size, so the curves are smoother, longer intervals (thinning), which reduces autocorrelation, and a larger burin. All this together to improve the Gelman test statistic. We also added idegree from 0 to 10, and esp from 0 to 3 to explicitly match those statistics in our model.

```

5.6 More on MCMC convergence

For more on this issue, I recommend reviewing chapter 1 and chapter 6 from the Handbook of MCMC (Brooks et al. 2011). Both chapters are free to download from the book's website.

For GOF take a look at section 6 of ERGM 2016 Sunbelt tutorial, and for a more technical review, you can take a look at (David R Hunter, Goodreau, and Handcock 2008).

5.7 Mathematical Interpretation

One of the most critical parts of statistical modeling is interpreting the results, if not the most important. In the case of ERGMs, a key aspect is based on change statistics. Suppose that we would like to know how likely the tie y_{ij} is to happen, given the rest of the network. We can compute such probabilities using what literature sometimes describes as the Gibbs-sampler.

In particular, the log-odds of the *ij* tie ocurring conditional on the rest of the network can be written as:

$$logit(\mathbb{P}(y_{ij} = 1|y_{-ij})) = \theta^{t} \Delta \delta(y_{ij} : 0 \to 1), \tag{5.1}$$

Sample statistics

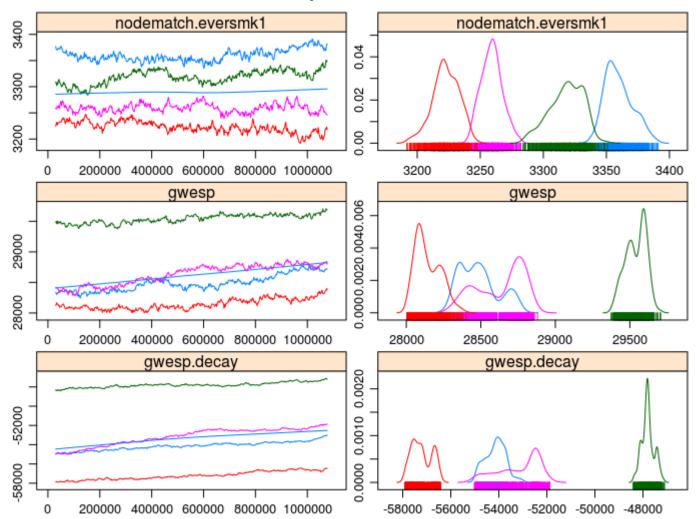

Figure 5.4: An example of a terrible ERGM (no convergence at all). Also, a good example of why running multiple chains can be useful

with $\delta(y_{ij}:0\to1)\equiv s(\mathbf{y})_{ij}^+-s(\mathbf{y})_{ij}^-$ as the vector of change statistics, in other words, the difference between the sufficient statistics when $y_{ij}=1$ and its value when $y_{ij}=0$. To show this, we write the following:

$$\begin{split} \mathbb{P}\left(y_{ij} = 1 | y_{-ij}\right) &= \frac{\mathbb{P}\left(y_{ij} = 1, x_{-ij}\right)}{\mathbb{P}\left(y_{ij} = 1, y_{-ij}\right) + \mathbb{P}\left(y_{ij} = 0, y_{-ij}\right)} \\ &= \frac{\exp\left\{\theta^{\mathbf{t}} s\left(\mathbf{y}\right)_{ij}^{+}\right\}}{\exp\left\{\theta^{\mathbf{t}} s\left(\mathbf{y}\right)_{ij}^{+}\right\} + \exp\left\{\theta^{\mathbf{t}} s\left(\mathbf{y}\right)_{ij}^{-}\right\}} \end{split}$$

Applying the logit function to the previous equation, we obtain:

$$= \log \left\{ \frac{\exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{+}\right\}}{\exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{+}\right\} + \exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{-}\right\}} - \log \left\{ \frac{\exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{+}\right\}}{\exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{+}\right\} + \exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{-}\right\}} \right\}$$

$$= \log \left\{ \exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{+}\right\} - \log \left\{ \exp\left\{\theta^{\mathbf{t}}s(\mathbf{y})_{ij}^{-}\right\} \right\}$$

$$= \theta^{\mathbf{t}} \left(s(\mathbf{y})_{ij}^{+} - s(\mathbf{y})_{ij}^{-}\right)$$

$$= \theta^{\mathbf{t}} \Delta \delta \left(y_{ij} : 0 \to 1 \right)$$

Henceforth, the conditional probability of node n gaining function k can be written as:

$$\mathbb{P}(y_{ij} = 1 | y_{-ij}) = \frac{1}{1 + \exp\{-\theta^{t} \Delta \delta(y_{ij} : 0 \to 1)\}}$$
 (5.2)

i.e., a logistic probability.

5.8 Markov independence

The challenge of analyzing networks is their interdependent nature. Nonetheless, in the absence of such interdependence, ERGMs are equivalent to logistic regression. Conceptually, if all the statistics included in the model do not involve two or more dyads, then the model is non-Markovian in the sense of Markov graphs.

Mathematically, to see this, it suffices to show that the ERGM probability can be written as the product of each dyads' probabilities.

$$\mathbb{P}(\mathbf{y}|\theta) = \frac{\exp\left\{\theta^{t}s(\mathbf{y})\right\}}{\sum_{y} \exp\left\{\theta^{t}s(\mathbf{y})\right\}} = \frac{\prod_{ij} \exp\left\{\theta^{t}s(\mathbf{y})_{ij}\right\}}{\sum_{y} \exp\left\{\theta^{t}s(\mathbf{y})\right\}}$$

Where $s()_{ij}$ is a function such that $s(\mathbf{y}) = \sum_{ij} s(\mathbf{y})_{ij}$. We now need to deal with the normalizing constant. To see how that can be saparated, let's start from the result:

$$\begin{split} &= \prod_{ij} \left(1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{ij}\right\}\right) \\ &= \left(1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{11}\right\}\right) \left(1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{12}\right\}\right) \dots \left(1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{nn}\right\}\right) \\ &= 1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{11}\right\} + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{11}\right\} \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{12}\right\} + \dots + \prod_{ij} \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{ij}\right\} \\ &= 1 + \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{11}\right\} + \exp\left\{\theta^{\mathbf{t}} \left(s(\mathbf{y})_{11} + s(\mathbf{y})_{12}\right)\right\} + \dots + \prod_{ij} \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})_{ij}\right\} \\ &= \sum_{\mathbf{y} \in \mathcal{Y}} \exp\left\{\theta^{\mathbf{t}} s(\mathbf{y})\right\} \end{split}$$

Where the last equality follows from $s(\mathbf{y}) = \sum_{ij} s(\mathbf{y})_{ij}$. This way, we can now write:

$$\frac{\prod_{ij} \exp\left\{\theta^{t} s(\mathbf{y})_{ij}\right\}}{\sum_{y} \exp\left\{\theta^{t} s(\mathbf{y})\right\}} = \prod_{ij} \frac{\exp\left\{\theta^{t} s(\mathbf{y})_{ij}\right\}}{1 + \exp\left\{\theta^{t} s(\mathbf{y})_{ij}\right\}}$$
(5.3)

Related to this, block-diagonal ERGMs can be estimated as independent models, one per block. To see more about this, read (SNIJDERS 2010). Likewise, since independence depends—pun intended—on partitioning the objective function, as pointed by Snijders, non-linear functions make the model dependent, e.g., $s(\mathbf{y}) = \sqrt{\sum_{ij} y_{ij}}$, the square root of the edgecount is no longer a bernoulli graph.

(Separable) Temporal Exponential Family Random Graph Models

This tutorial is great! https://statnet.org/trac/raw-attachment/wiki/Sunbelt2016/tergm_tutorial.pdf

Stochastic Actor Oriented Models

Stochastic Actor Oriented Models (SOAM), also known as Siena models were introduced by CITATION NEEDED.

As a difference from ERGMs, Siena models look at the data generating process from the individuals' point of view. Based on McFadden's ideas of probabilistic choice, the model is founded in the following equation

$$U_i(x) - U_i(x') \sim \text{Extreame Value Distribution}$$

In other words, individuals choose between states x and x' in a probabilistic way (with some noise),

$$\frac{\exp\left\{f_i^Z(\beta^z, x, z)\right\}}{\sum_{Z' \in \mathcal{C}} \exp\left\{f_i^Z(\beta, x, z')\right\}}$$

Hypothesis testing in networks

Overall, there are many ways in which we can see hypothesis testing within the networks context:

- 1. **Comparing two or more networks**, e.g., we want to see if the density of two networks are *equal*.
- 2. **Prevalence of a motif/pattern**, e.g., check whether the observed number of transitive triads is different from that expected as of by chance.
- 3. **Multivariate using ERGMs**, e.g., jointly test whether homophily and two stars are the motifs that drive network structure.

The latter we already review in the ERGM chapter. In this part, we will look at types one and two; both using non-parametric methods.

8.1 Comparing networks

Imagine that we have two graphs, $(G_1, G_2) \in \mathcal{G}$, and we would like to assess whether a given statistic $s(\cdot)$, e.g., density, is equal in both of them. Formally, we would like to asses whether $H_0: s(G_1) - s(G_2) = k$ vs $H_a: s(G_1) - s(G_2) \neq k$.

As usual, the true distribution of $s(\cdot)$ is unknown, thus, one approach that we could use is a non-parametric bootstrap test.

8.1.1 Network bootstrap

The non parametric bootstrap and jackknife methods for social networks were introduced by (Snijders and Borgatti 1999). The method itself is used to generate standard errors for network level statistics. Both methods are implemented in the R package netdiffuseR.

8.1.2 When the statistic is normal

When the we deal with things that are normally distributed, e.g., sample means like density¹, we can make use of the Student's distribution for making inference. In particular, we can use Bootstrap/Jackknife to approximate the standard errors of the statistic for each network:

1. Since $s(G_i) \sim N(\mu_i, \sigma_i^2/m_i)$ for $i \in \{1, 2\}$, in the case of the density, $m_i = n_i * (n_i - 1)$. The statistic is then:

$$s(G_1) - s(G_0) \sim N(\mu_1 - \mu_0, \sigma_1^2/m_1 + \sigma_1^2/m_2)$$

Thus

$$\frac{s(G_1) - s(G_0) - \mu_1 + \mu_2}{\sqrt{\sigma_1^2/m_1 + \sigma_1^2/m_2}} \sim t_{m_1 + m_2 - 2}$$

But, if we are testing $H_0: \mu_1 - \mu_2 = k$, then, under the null

$$\frac{s(G_1) - s(G_0) - k}{\sqrt{\sigma_1^2/m_1 + \sigma_1^2/m_2}} \sim t_{m_1 + m_2 - 2}$$

Where We now proceede to approximate the variances.

2. Using the *plugin principle* (Efron and Tibshirani 1994), we can approximate the variances using Bootstrap/Jackknife, i.e., compute $\hat{\sigma}_1^2 \approx \sigma_1^2/m_1$ and $\hat{\sigma}_2^2 \approx \sigma_2^2/m_2$. Using netdiffuseR

```
# Obtain a 100 replicates
sg1 <- bootnet(g1, function(i, ...) sum(i)/(nnodes(i) * (nnodes(i) - 1)), R = 100)
sg2 <- bootnet(g2, function(i, ...) sum(i)/(nnodes(i) * (nnodes(i) - 1)), R = 100)

# Retrieving the variances
hat_sigma1 <- sg1$var_t
hat_sigma2 <- sg2$var_t

# And the actual values
sg1 <- sg1$t0
sg2 <- sg2$t0</pre>
```

3. With the approximates in hand, we can then use the "t-test table" to retrieve the corresponding value, in R:

¹Density is indeed a sample mean as we are, in principle computing the average of a sequence of Bernoulli variables. Formally: density(G) = $\frac{1}{n(n-1)} \sum_{ij} A_{ij}$.

```
# Building the statistic
k <- 0 # For equal variances
tstat <- (sg1 - sg2 - k)/(sqrt(hat_sigma1 + hat_sigma2))

# Computing the pvalue
m1 <- nnodes(g1)*(nnodes(g1) - 1)
m2 <- nnodes(g2)*(nnodes(g2) - 1)
pt(tstat, df = m1 + m2 - 2)</pre>
```

8.1.3 When the statistic is NOT normal

In the case that the statistic is not normally distributed, we cannot use the t-statistic any longer. Nevertheless, the Bootstrap can come to help. While in general it is better to use distributions of pivot statistics (see (Efron and Tibshirani 1994)), we can still leverage the power of this method to make inferences. For this example, $s(\cdot)$ will be the range of the threshold in a diffusion graph.

As before, imagine that we are dealing with an statistic $s(\cdot)$ for two different networks, and we would like to asses whether we can reject H_0 or fail to reject it. The procedure is very similar:

- 1. One approach that we can test is whether $k \in \text{ConfInt}(s(G_1) s(G_2))$. Building confidence intervals with bootstrap could be more intuitive.
- 2. Like before, we use bootstrap to generate a distribution of $s(G_1)$ and $s(G_2)$, in R:

```
# Obtain a 1000 replicates
sg1 <- bootnet(g1, function(i, ...) range(threshold(i)), R = 1000)
sg2 <- bootnet(g2, function(i, ...) range(threshold(i)), R = 1000)

# Retrieving the distributions
sg1 <- sg1$boot$t
sg2 <- sg2$boot$t

# Define the statistic
sdiff <- sg1 - sg2</pre>
```

3. Once we have sdiff, we can proceed and compute the, for example, 95% confidence interval, and evaluate whether *k* falls within. In R:

```
diff_ci \leftarrow quantile(sdiff, probs = c(0.025, .975))
```

This corresponds to what Efron and Tibshirani call "percentile interval." This is easy to compute, but a better approach is using the "BCa" method, "Bias Corrected and Accelerated." (TBD)

8.2 Examples

8.2.1 Average of node-level stats

Supposed that we would like to compare something like average indegree. In particular, for both networks, G_1 and G_2 , we compute the average indegree per node:

$$s(G_1) = \text{AvgIndeg}(G_1) = \frac{1}{n} \sum_{i} \sum_{j \neq i} A_{ji}^1$$

where A_{ji}^1 equals one if vertex j sends a tie to i. In this case, since we are looking at an average, we have that $AvgIndeg(G_1) \sim N(\mu_1, \sigma_1^2/n)$. Thus, taking advantage of the normality of the statistic, we can build a test statistic as follows:

$$\frac{s(G_1) - s(G_2) - k}{\sqrt{\hat{\sigma}_1^2 + \hat{\sigma}_2^2}} \sim t_{n_1 + n_2 - 2}$$

Where $\hat{\sigma}_i$ is the bootstrap standard error, and k=0 when we are testing equality. This distributes t with n_1+n_2-2 degrees of freedom. As a difference from the previous example using density, the degrees of freedom for this test are less as, instead of having an average across all entries of the adjacency matrix, we have an average across all vertices.

Appendix A

Datasets

A.1 SNS data

A.1.1 About the data

- This data is part of the NIH Challenge grant # RC 1RC1AA019239 "Social Networks and Networking That Puts Adolescents at High Risk".
- In general terms, the SNS's goal was(is) "Understand the network effects on risk behaviors such as smoking initiation and substance use".

A.1.2 Variables

The data has a *wide* structure, which means that there is one row per individual, and that dynamic attributes are represented as one column per time.

- photoid Photo id at the school level (can be repeated across schools).
- school School id.
- hispanic Indicator variable that equals 1 if the indivual ever reported himself as hispanic.
- female1, ..., female4 Indicator variable that equals 1 if the individual reported to be female at the particular wave.
- grades1,..., grades4 Academic grades by wave. Values from 1 to 5, with 5 been the best.
- eversmk1, ..., eversmk4 Indicator variable of ever smoking by wave. A one indicated that the individual had smoked at the time of the survey.
- everdrk1, ..., everdrk4 Indicator variable of ever drinking by wave. A one indicated that the individual had drink at the time of the survey.
- home1, ..., home4 Factor variable for home status by wave. A one indicates home ownership, a 2 rent, and a 3 a "I don't know".

During the survey, participants were asked to name up to 19 of their school friends:

- sch_friend11, ..., sch_friend119 School friends nominations (19 in total) for wave 1. The codes are mapped to the variable photoid.
- sch_friend21, ..., sch_friend219 School friends nominations (19 in total) for wave 2. The codes are mapped to the variable photoid.
- sch_friend31, ..., sch_friend319 School friends nominations (19 in total) for wave 3. The codes are mapped to the variable photoid.
- sch_friend41, ..., sch_friend419 School friends nominations (19 in total) for wave 4. The codes are mapped to the variable photoid.
